HAMMERSTEIN AND WIENER MODELS IN MODELING OF NONLINEAR PROCESS

BABIK, Z[denek] & DOSTAL, P[etr]

Abstract: The application of Hammerstein and Wiener models in simulation of real nonlinear systems is described in this paper. Equations which are used for design of nonlinear model are presented too. This method has been tested on real servo-speed mechanism AMIRA DR300.

Key words: Hammerstein and Wiener models, static nonlinearity, nonlinear system, servo-speed mechanism AMIRA DR300

1. INTRODUCTION

The nonlinear-system theory is a field of general system theory which is examined much fewer than classical linear theory. But in the practice, the most of real processes have a nonlinear behavior and their linearization is often possible only in a near neighborhood of operating points. The simulation of such processes by using of classical linear models cannot be successful.

One solution of this problem is presented in this paper. It is based on the fact that many real processes can be factorable – they are consisting from nonlinear static parts and linear dynamic parts. On the bases of their mutual position Hammerstein or Wiener model can be distinguished (Nelles, 2001; Bányaś et al., 2002).

2. HAMMERSTEIN AND WIENER MODELS

In Fig. 1 and Fig. 2 we can see the basic Hammerstein and Wiener models.

![Fig. 1. Hammerstein model of nonlinear system](image1)

The basic Hammerstein model $N_H$ is a cascade structure of the nonlinear static block and the linear dynamic block which can be described by next formulas:

$$X_H(k) = f_H(U(k)) \tag{1}$$

$$Y(k) = b_0X_H(k) + b_1X_H(k-1) + \cdots + b_mX_H(k-m) - a_1Y(k-1) - \cdots - a_nY(k-n) \tag{2}$$

The basic Wiener model $N_W$ is a cascade structure of the linear dynamic block and the nonlinear static block which can be described by next formulas:

$$X_W(k) = b_0U(k) + b_1U(k-1) + \cdots + b_mU(k-m) - a_1X_W(k-1) - \cdots - a_nX_W(k-n) \tag{3}$$

$$Y(k) = f_W(X_W(k)) \tag{4}$$

The H-models can describe many different processes, especially if their main nonlinear behavior is caused by actuators (dead zone, saturation, etc.).

The W-models are appropriate for systems, whose outputs are measured by sensors with nonlinear characteristic, and for controller design.

3. HAMMERSTEIN PROCESS MODEL

The equation (1) was transformed into the transfer function form. Then the Hammerstein model can be written like:

$$G_H(z^{-1}) = \frac{Y(z^{-1})}{X_H(z^{-1})} = \frac{b_1z^{-1} + \cdots + b_mz^{-m}}{1 + a_1z^{-1} + \cdots + a_nz^{-n}} \tag{5}$$

$$X_H(k) = f_H(U(k)) \tag{6}$$

where: $G_H(z^{-1})$ is the dynamic linear part and $f_H$ is the static nonlinear part.

The output value $Y(k)$ can be calculated form equation:

$$Y(k) = b_1f_H(U(k)) + \cdots + b_mf_H(U(k-m)) - a_1Y(k-1) + \cdots + a_nY(k-n) \tag{7}$$

The input value $U(k)$ will be considered like:

$$U(k-m) = \cdots = U(k-1) = U(k) \tag{8}$$

where: $m$ is a degree of numerator of $G_H(z^{-1})$. Input signal so can be considered stable and termed $U^s(k)$. Assume that some function $f_{stat}$ exist there, which assigns every value $U^s(k)$ to the value $Y^s(k)$ such that:

$$Y^s(k) = f_{stat}(U^s(k)) \tag{9}$$

The $f_{stat}$ is an approximation of a static characteristic of modeled system. Now we can write $f_{stat} = f_H$ and for output value is valid:

$$Y(k) = b_1f_{stat}(U^s(k)) + \cdots + b_mf_{stat}(U^s(k-m)) - a_1Y^s(k-1) + \cdots + a_nY^s(k-n) \tag{10}$$

From equation (9) and (10) and the transform of the result is valid:

$$G_H(z^{-1}) = \frac{Y(z^{-1})}{Y^s(z^{-1})} = \frac{b_1z^{-1} + \cdots + b_mz^{-m}}{1 + a_1z^{-1} + \cdots + a_nz^{-n}} \tag{11}$$

4. NONLINEAR STATIC CHARACTERISTIC OF SYSTEM AMIRA DR300

The static characteristic of AMIRA DR300 was measured by using a multilevel measuring signal.
7. THE COMPARE OF HAMMERSTEIN AND LINEAR MODEL OF SYSTEM AMIRA DR300

The accuracy of Hammerstein and linear models of AMIRA DR300 will be determinate from formula:

\[ \sigma^2 = \frac{1}{n} \sum_{i=1}^{n} (Y_{\text{Hammers}} - Y_{\text{MOD}})^2 \]  
\[ \sigma^2 = 0.001475 \]  
\[ \sigma^2 = 0.084212 \]  

8. DISCUSSION

The following facts could be said from the measured data which are displayed in Fig. 5 and Fig. 6 and from result (22) and (23): The quality of simulation is markedly better when the Hammerstein model is used than when the linear model is used only.

On the other hand, there exist some restrictions: This method can be used only for the factorable systems and the basic version of this method is non-universal.

The universality of this method must be increased by future research. One possible way is using of methods from genetic programming field or from neural network field.
